Pollution Episode

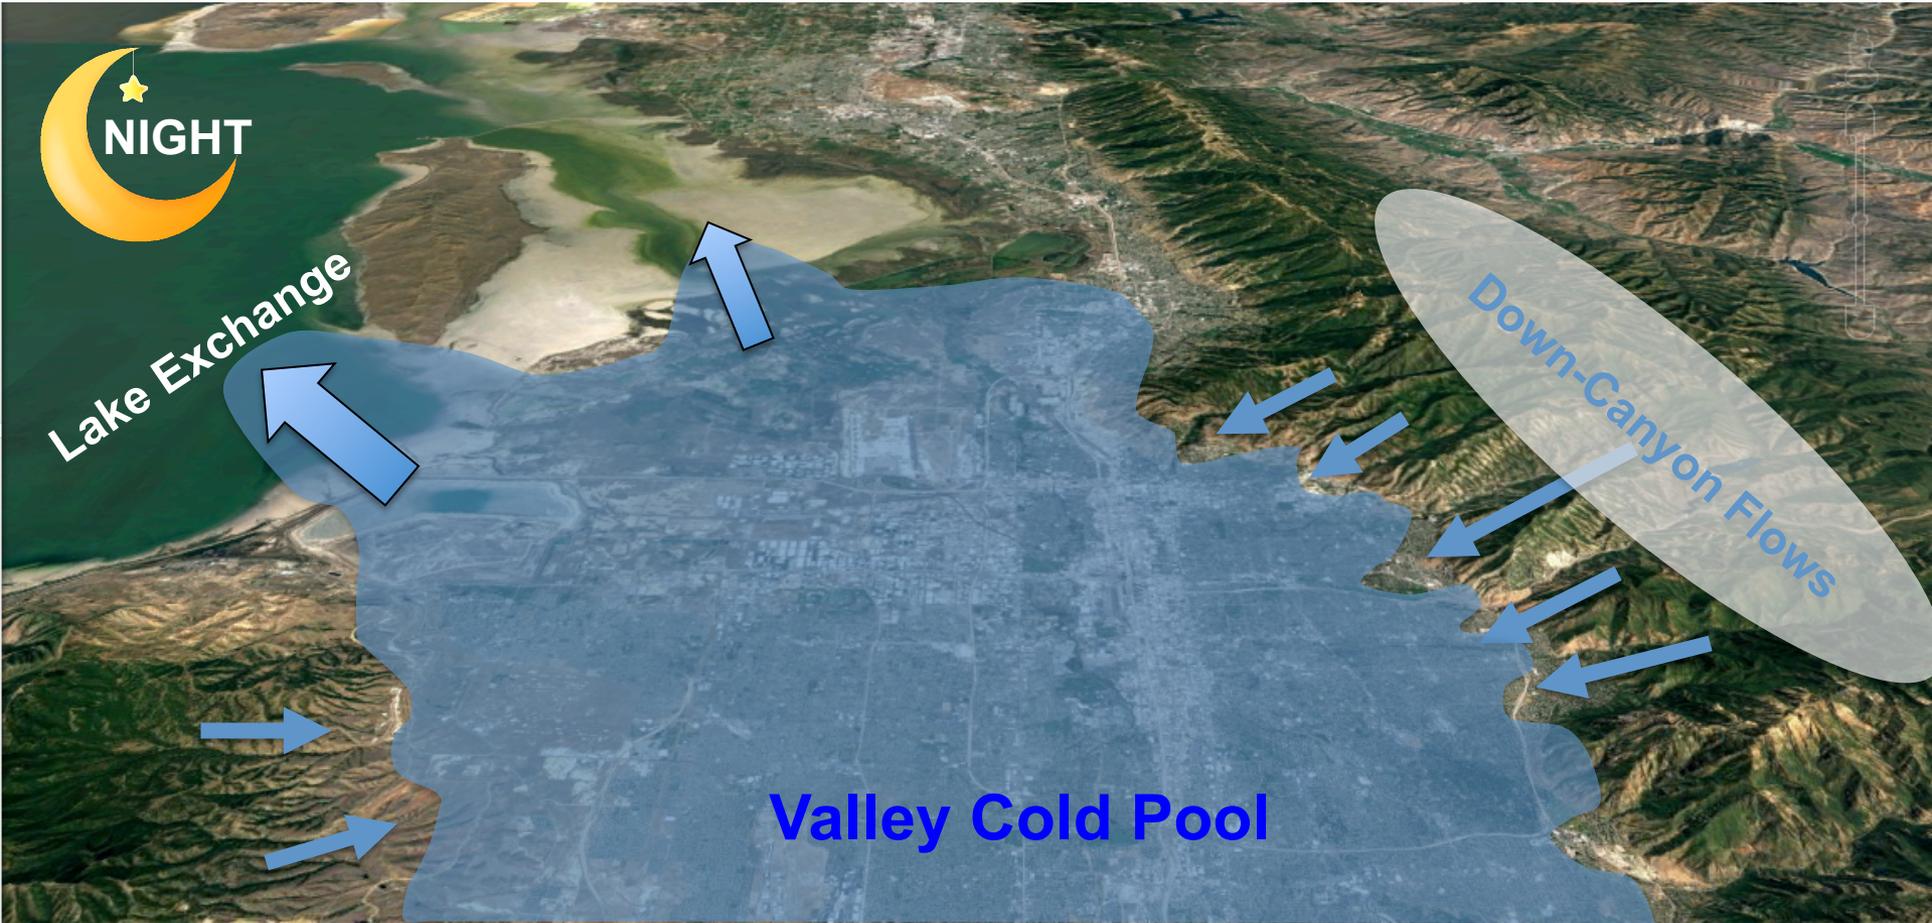

Reactive pathways of the secondary aerosol formation (see Munkh Baasandorj's Talk)

- Oxidants (O_3) are necessary to form HNO_3

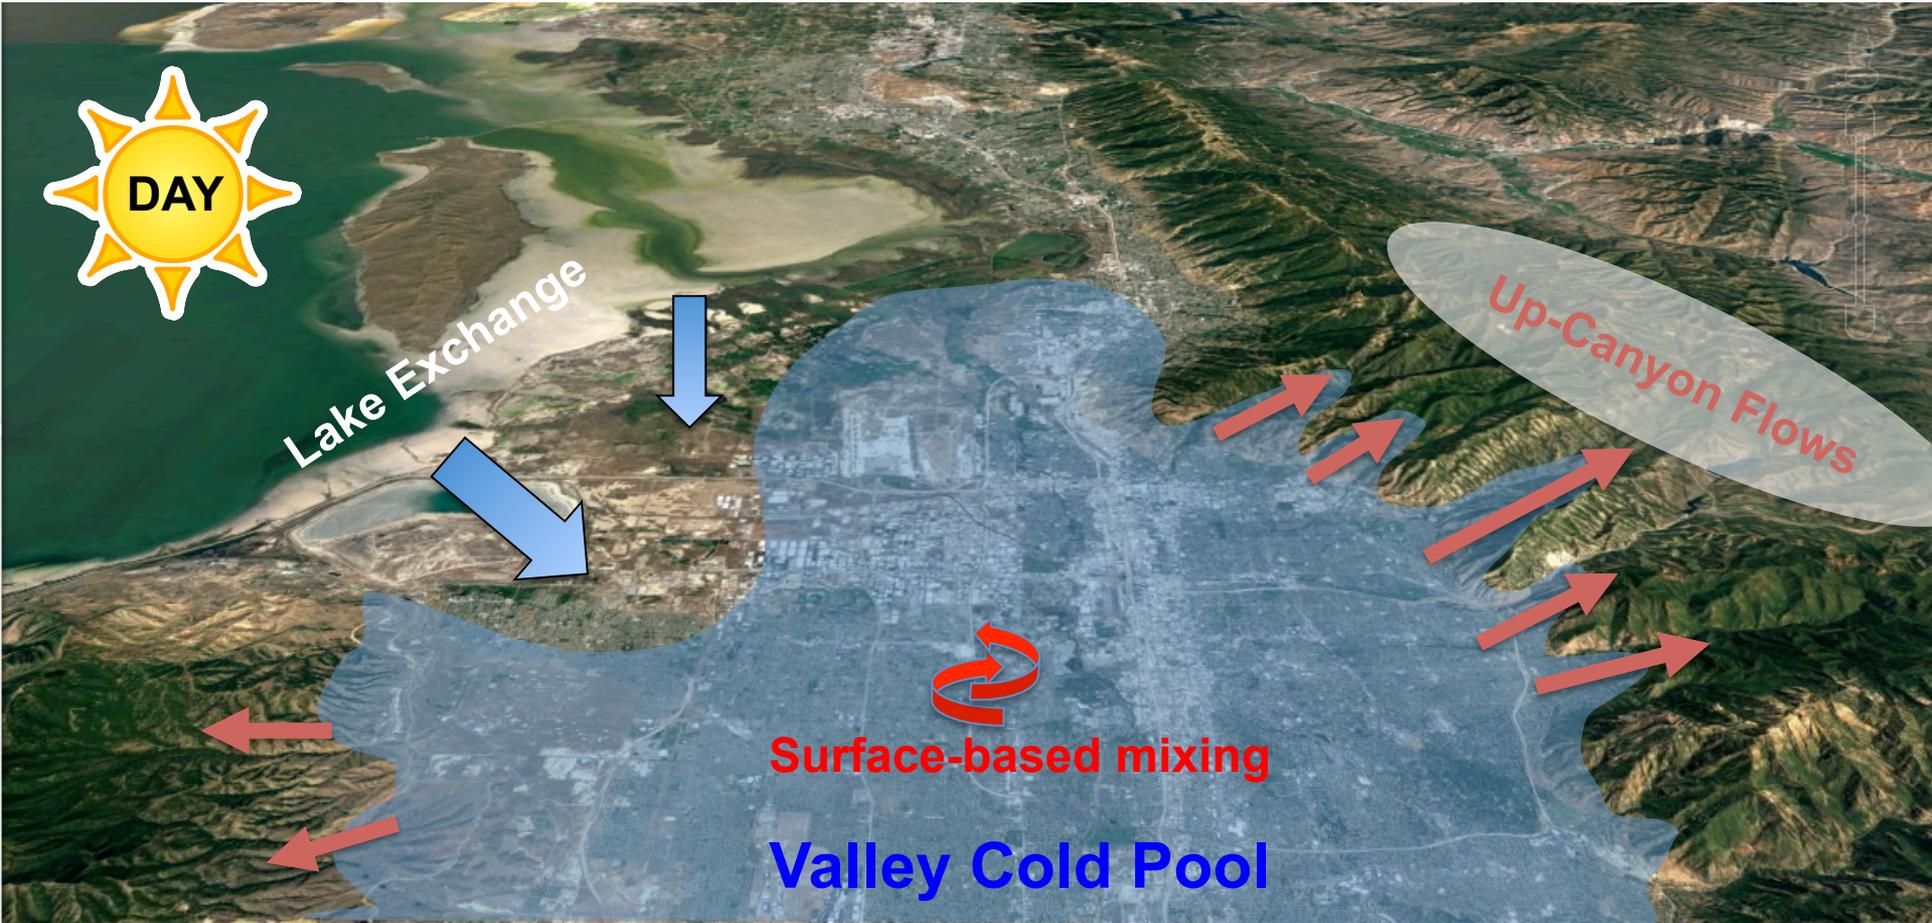

Night-time exchange processes

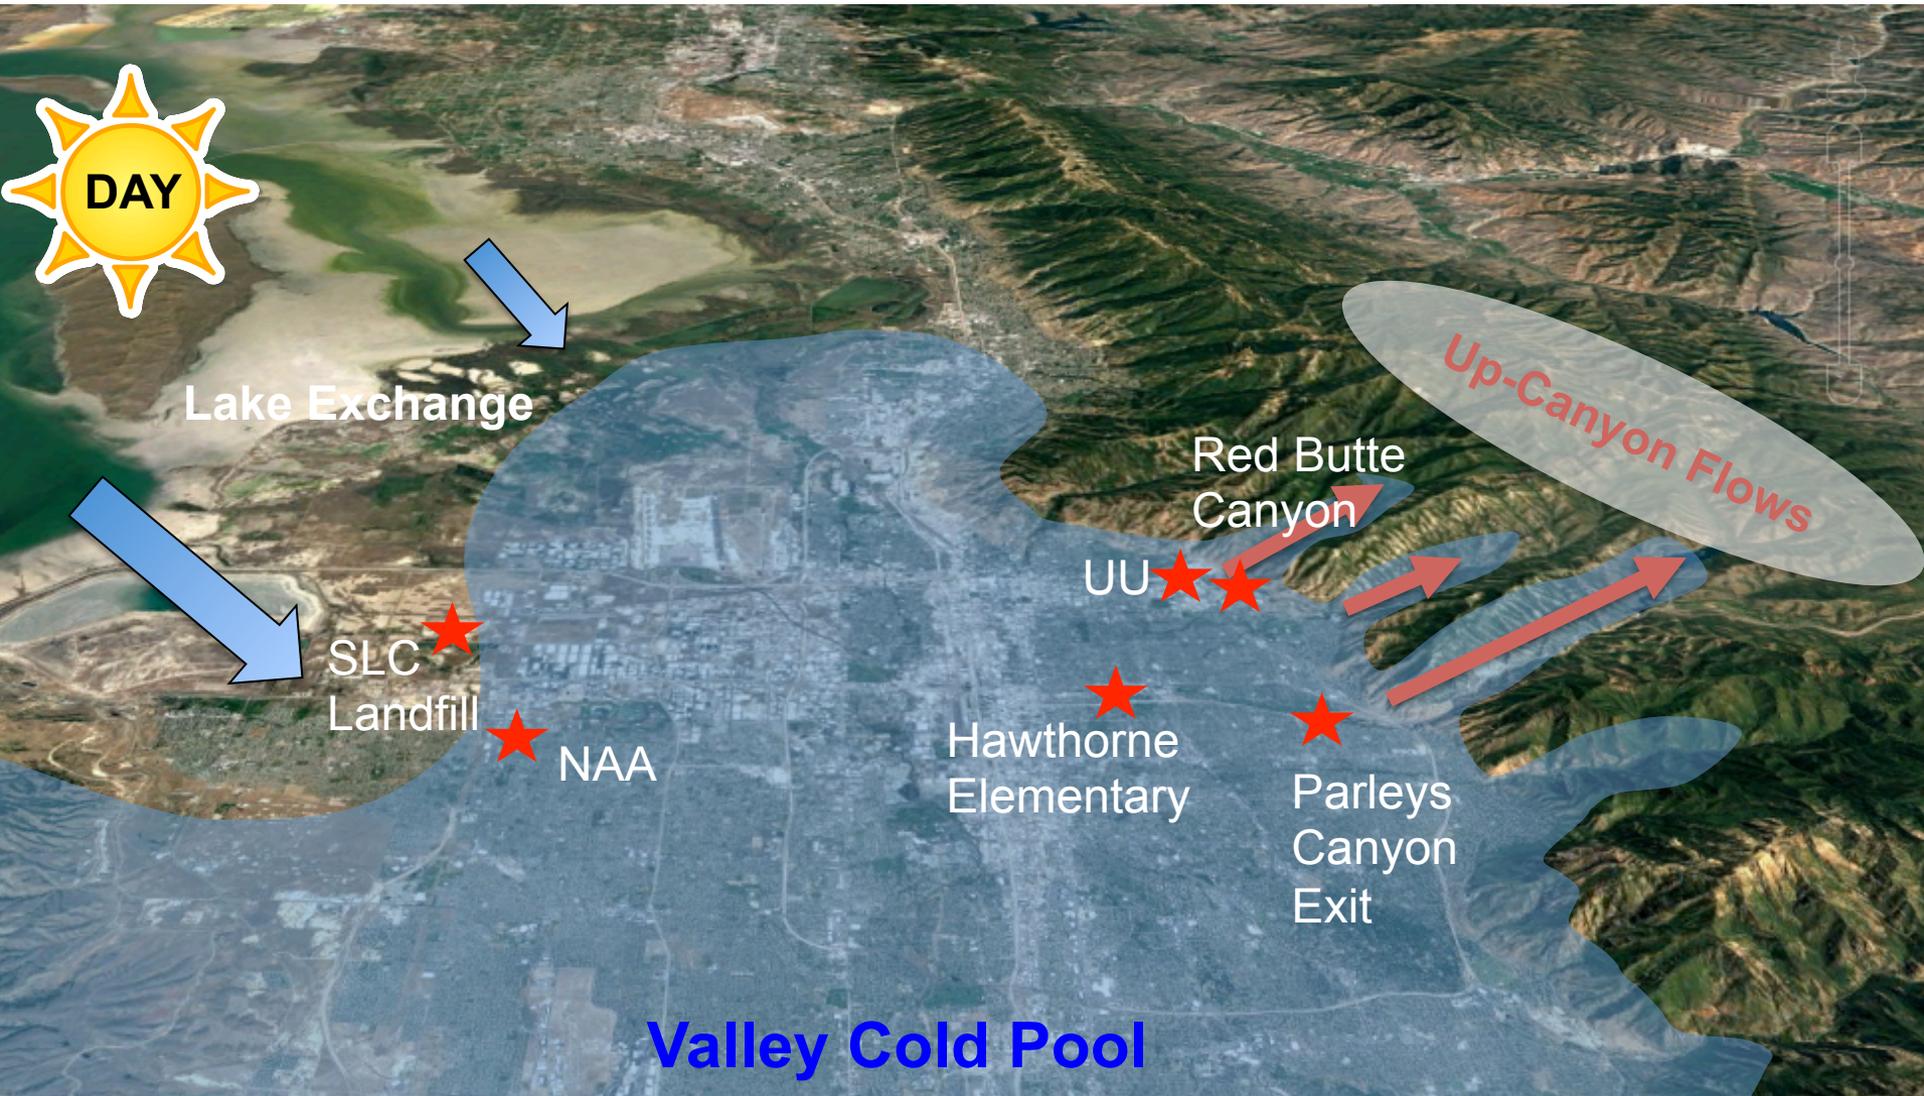

Day-time exchange processes

Observations

- 2015-2016 Salt Lake Valley PM_{2.5} Pollution Study
- 2016-2017 Utah Wintertime Fine Particulate Study

Observations / Methods

- Temperature profiles (weather balloons pseudo-vertical profiles)
- Wind profiles (Doppler Wind LiDAR, SoDAR)
- Aerosol loading (laser light backscatter ceilometer)
- PM_{2.5} concentrations (fine particulate pollution)
- Ozone concentrations (O₃)
- Surface winds / temperatures (AWS, MesoWest)

Observation Platforms

- Surface - based
- Mobile (KSL news helicopter, TRAX light rail)

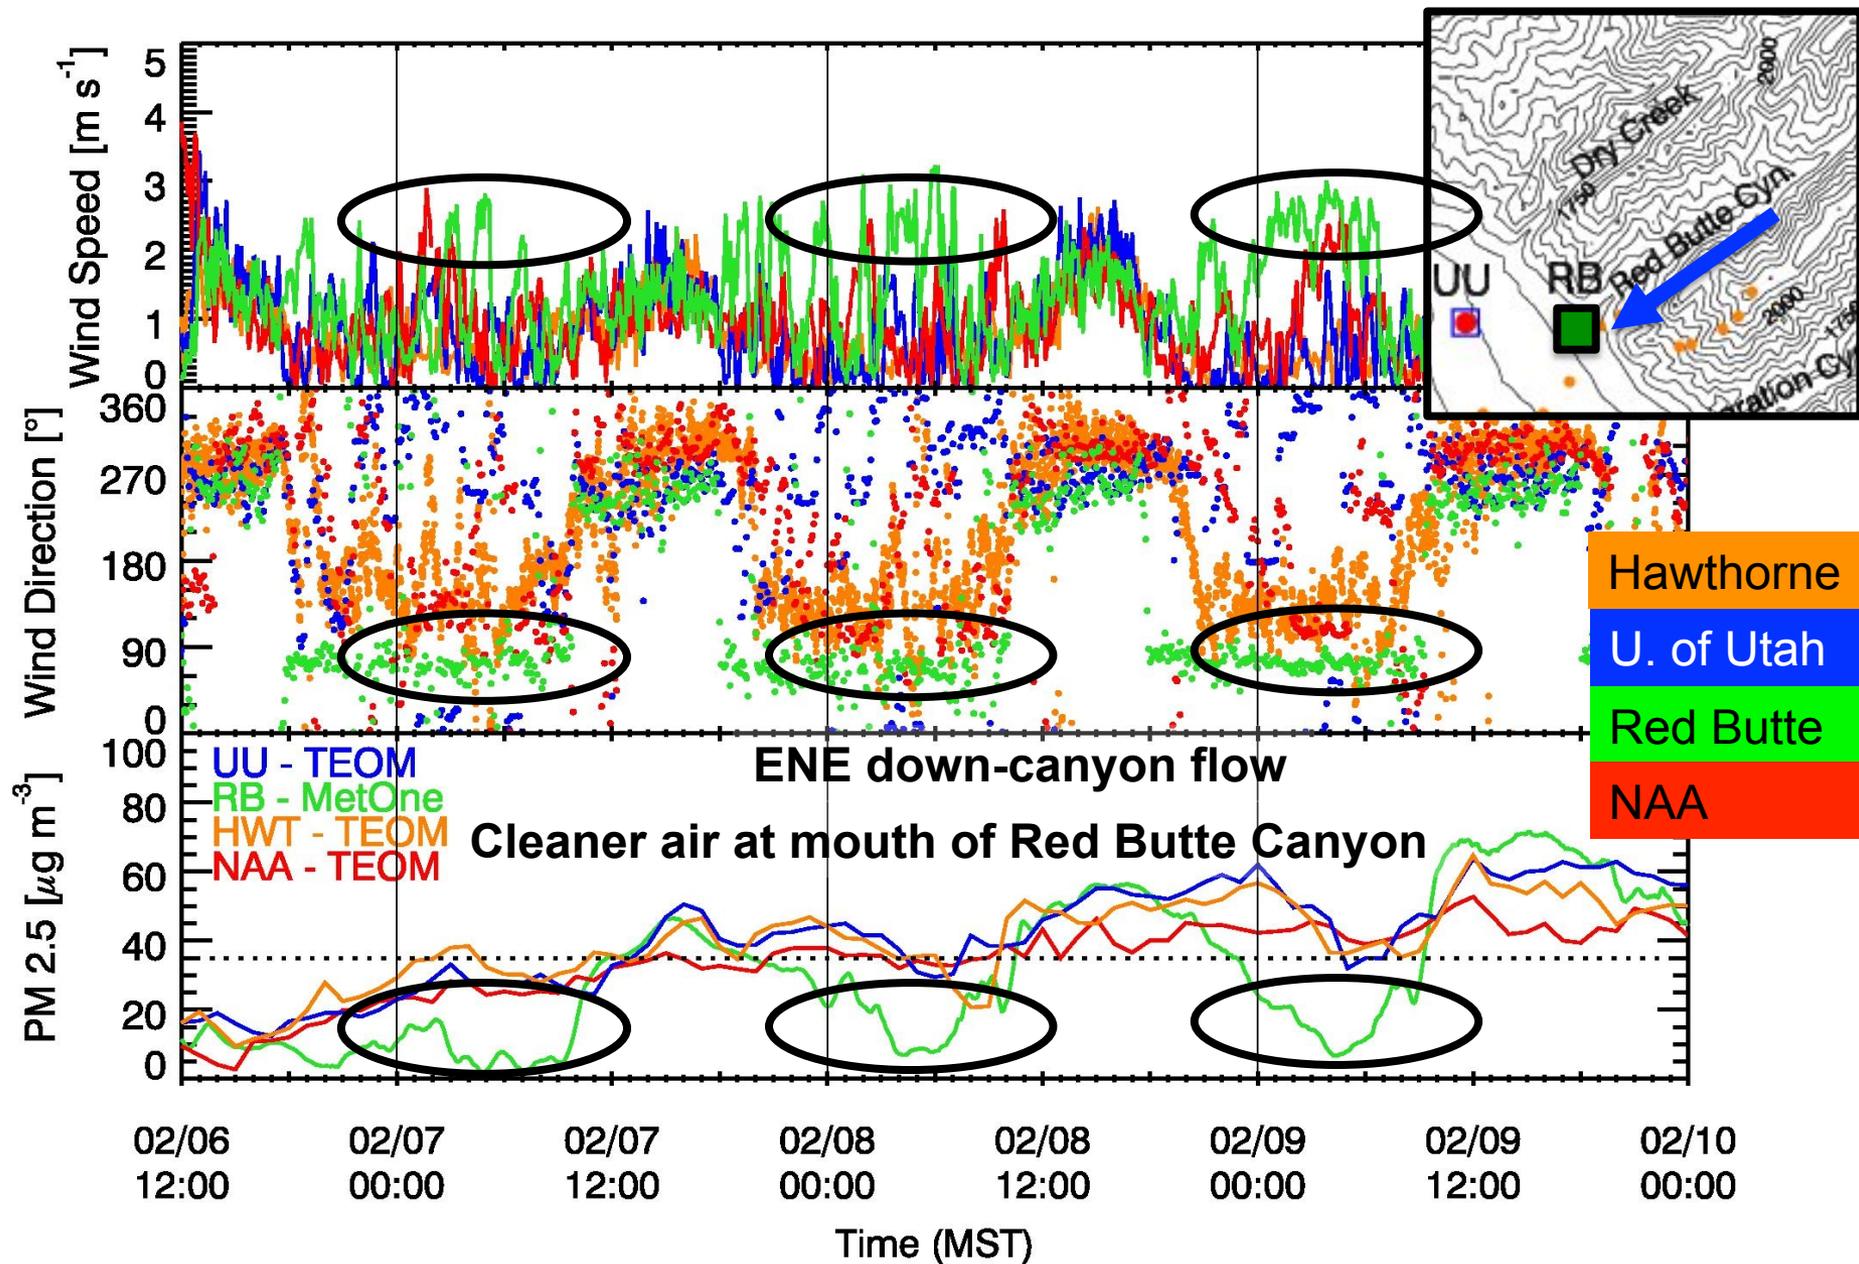

See Mitchell et al. - next talk!

Slope and Canyon Flows

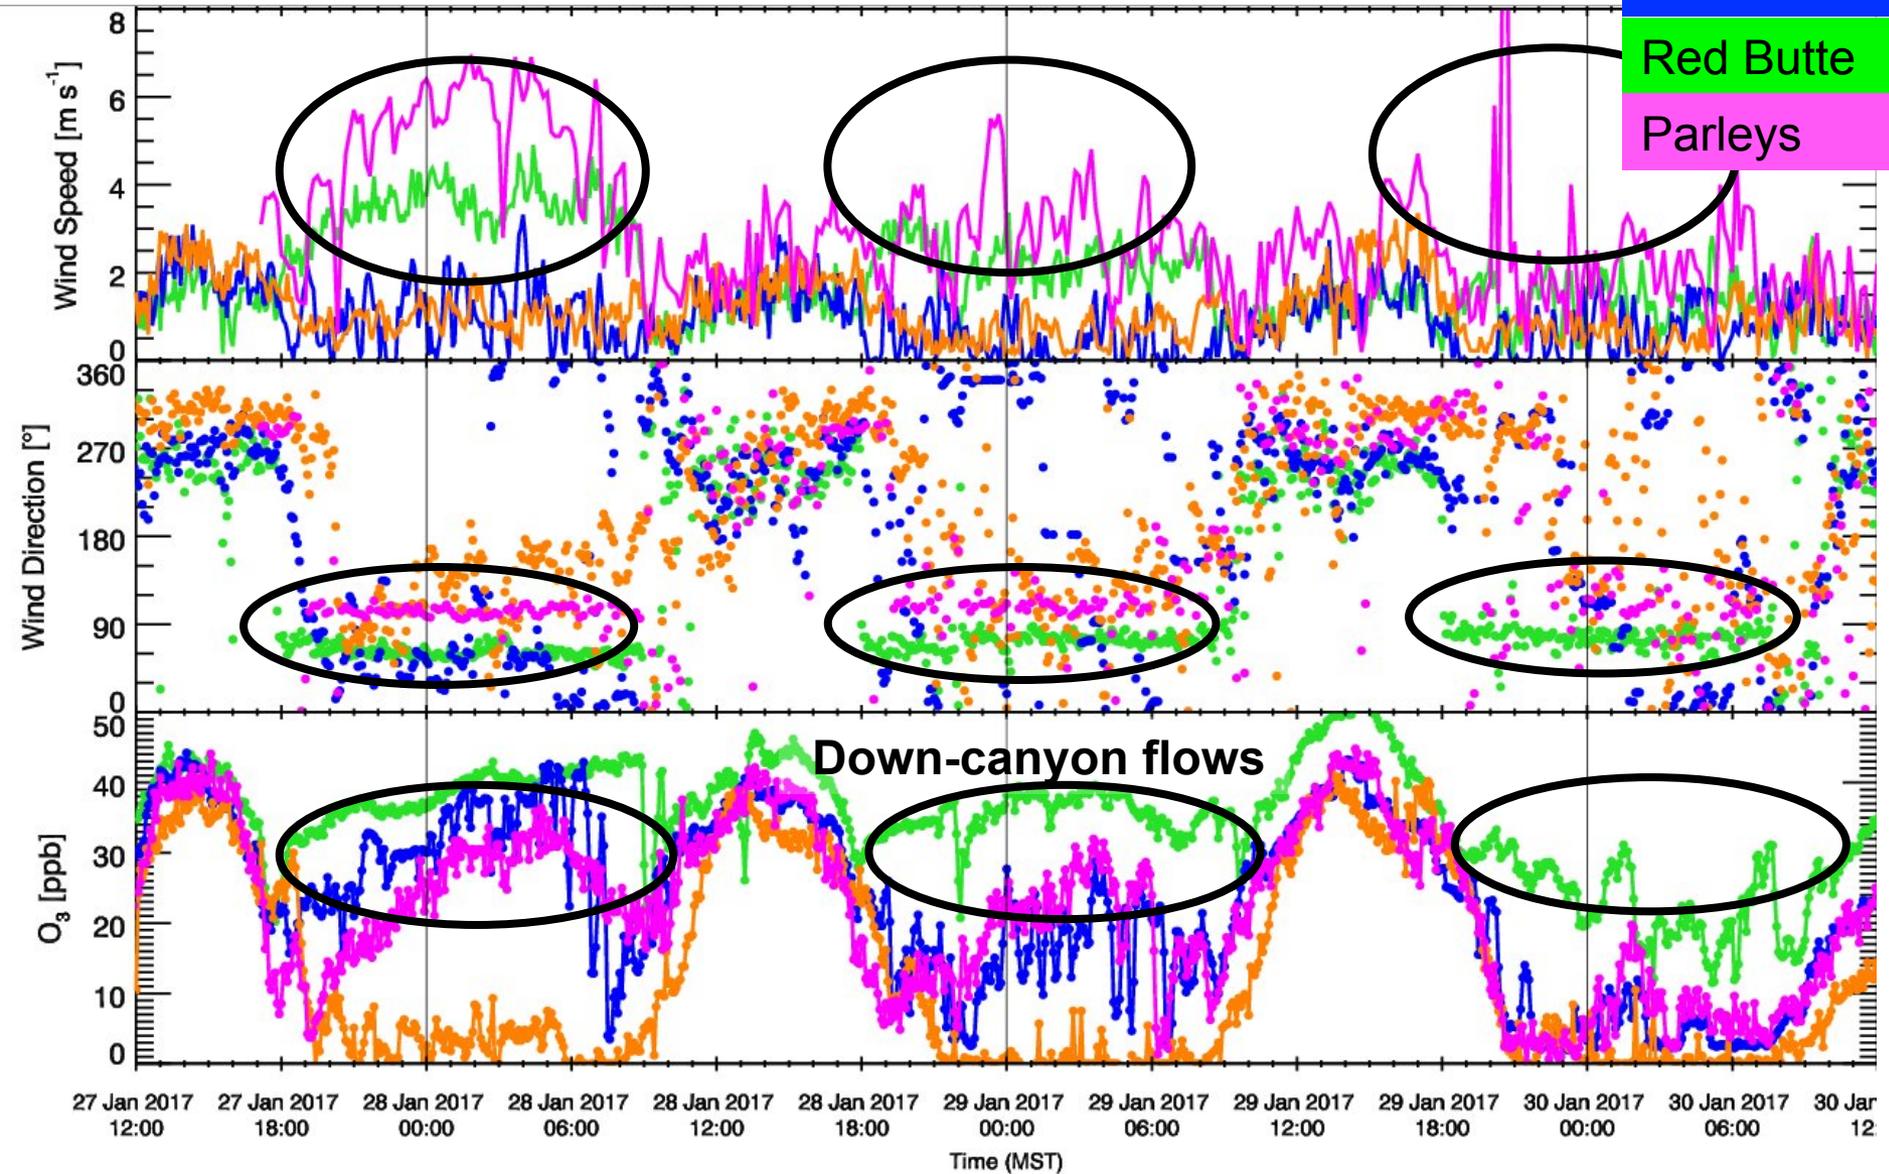

Thermal contrasts between basin floor and surrounding valleys drive daytime up-valley and up-slope and nighttime down-slope and down-valley flows.

Small Tributary Canyon – Red Butte Canyon (Feb 2016)

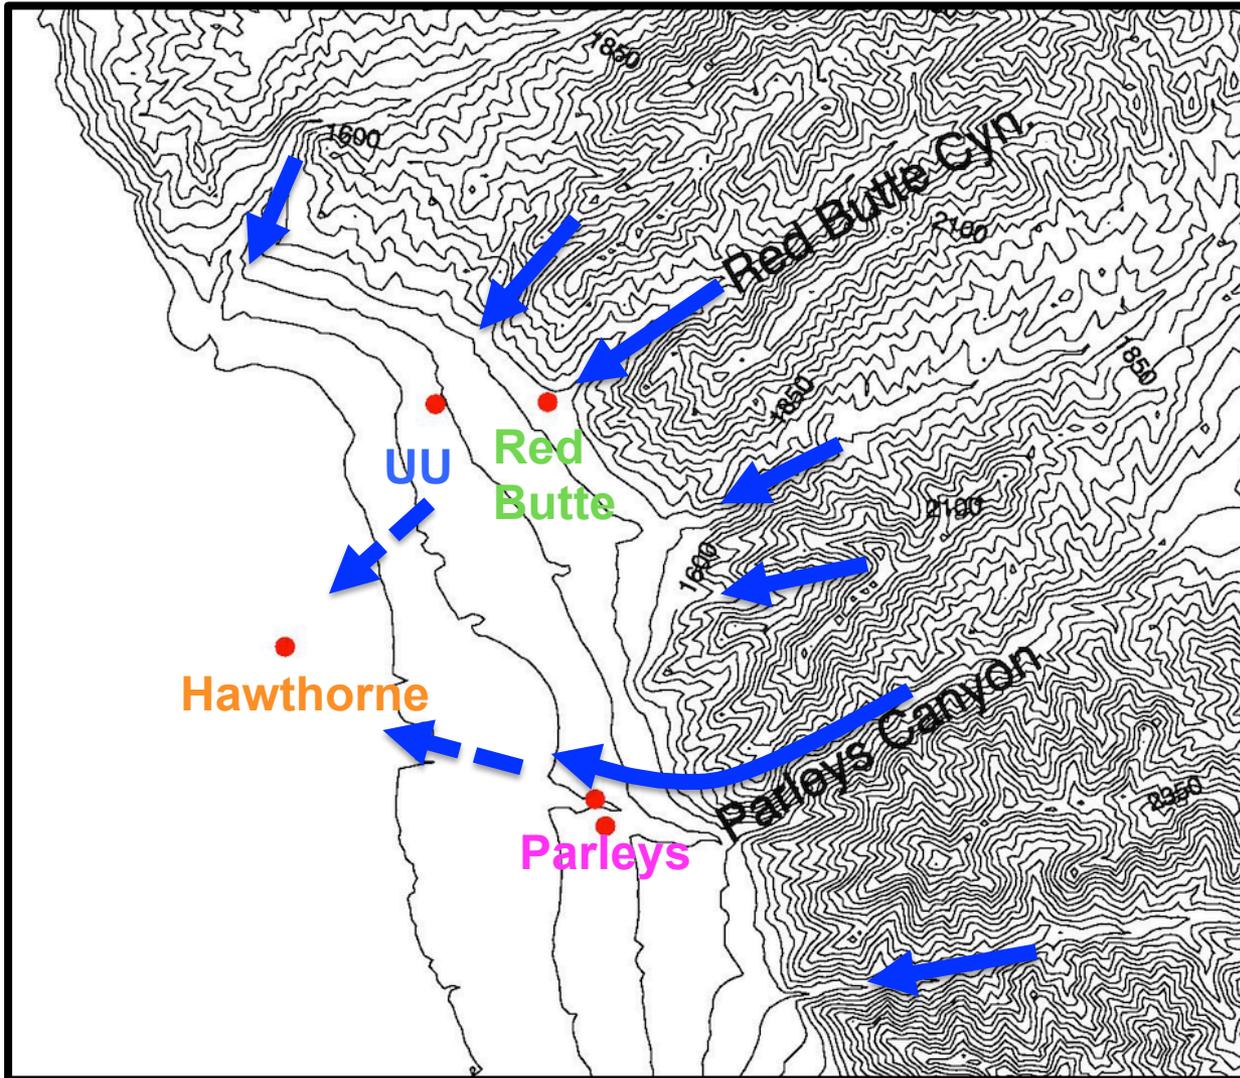

Large Tributary Canyon – Parleys Canyon

Hawthorne
U. of Utah
Red Butte
Parleys

Preliminary data (UWFPS)

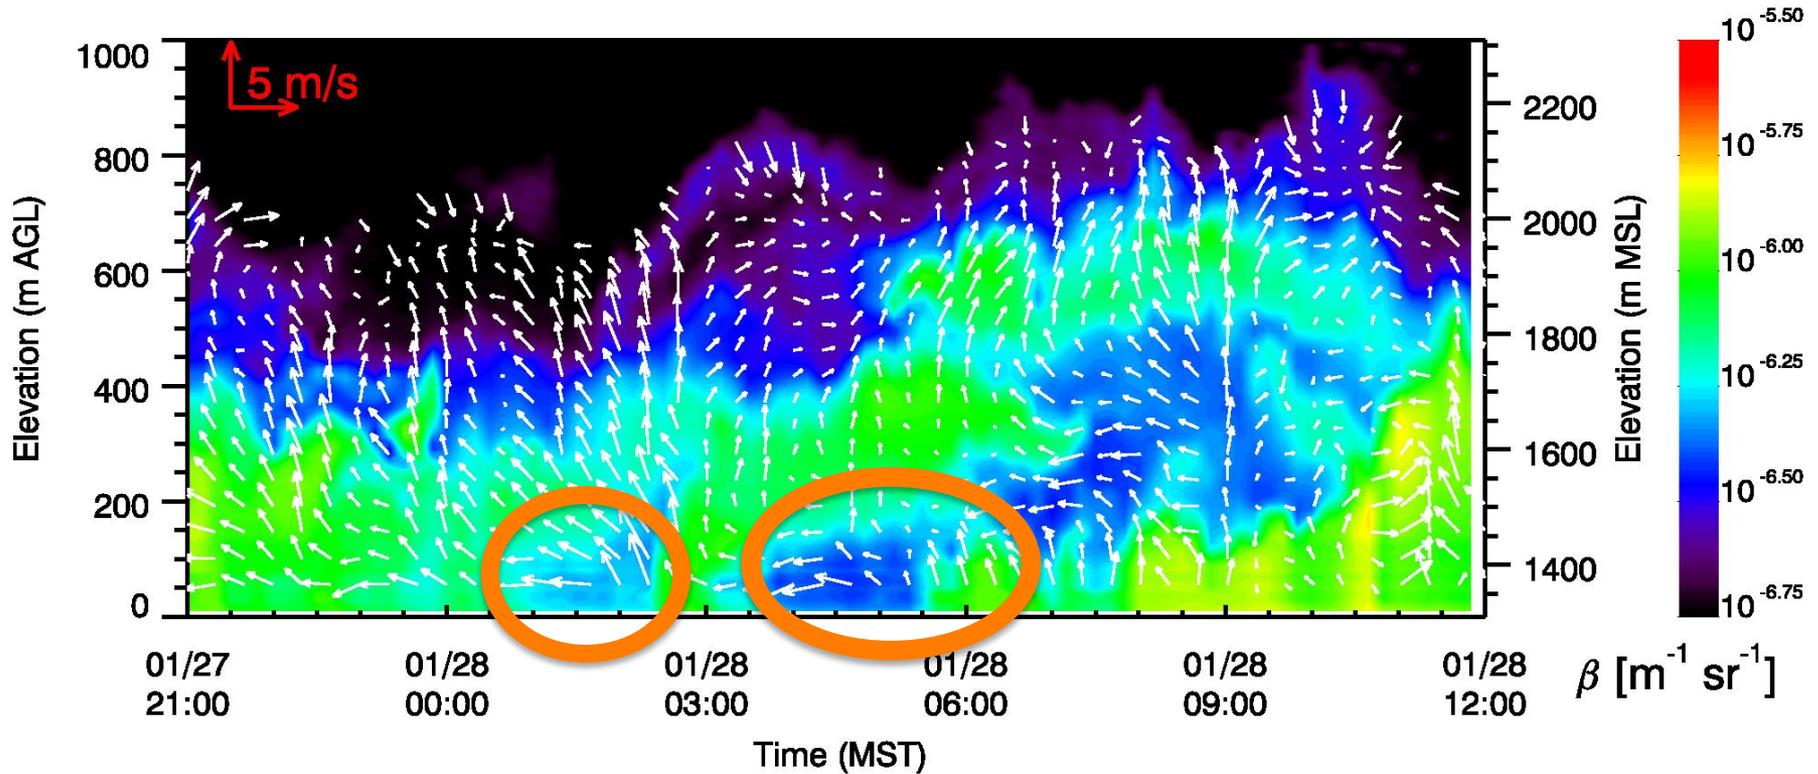

Nighttime, at mouth of tributary canyons:

→ Lower $PM_{2.5}$

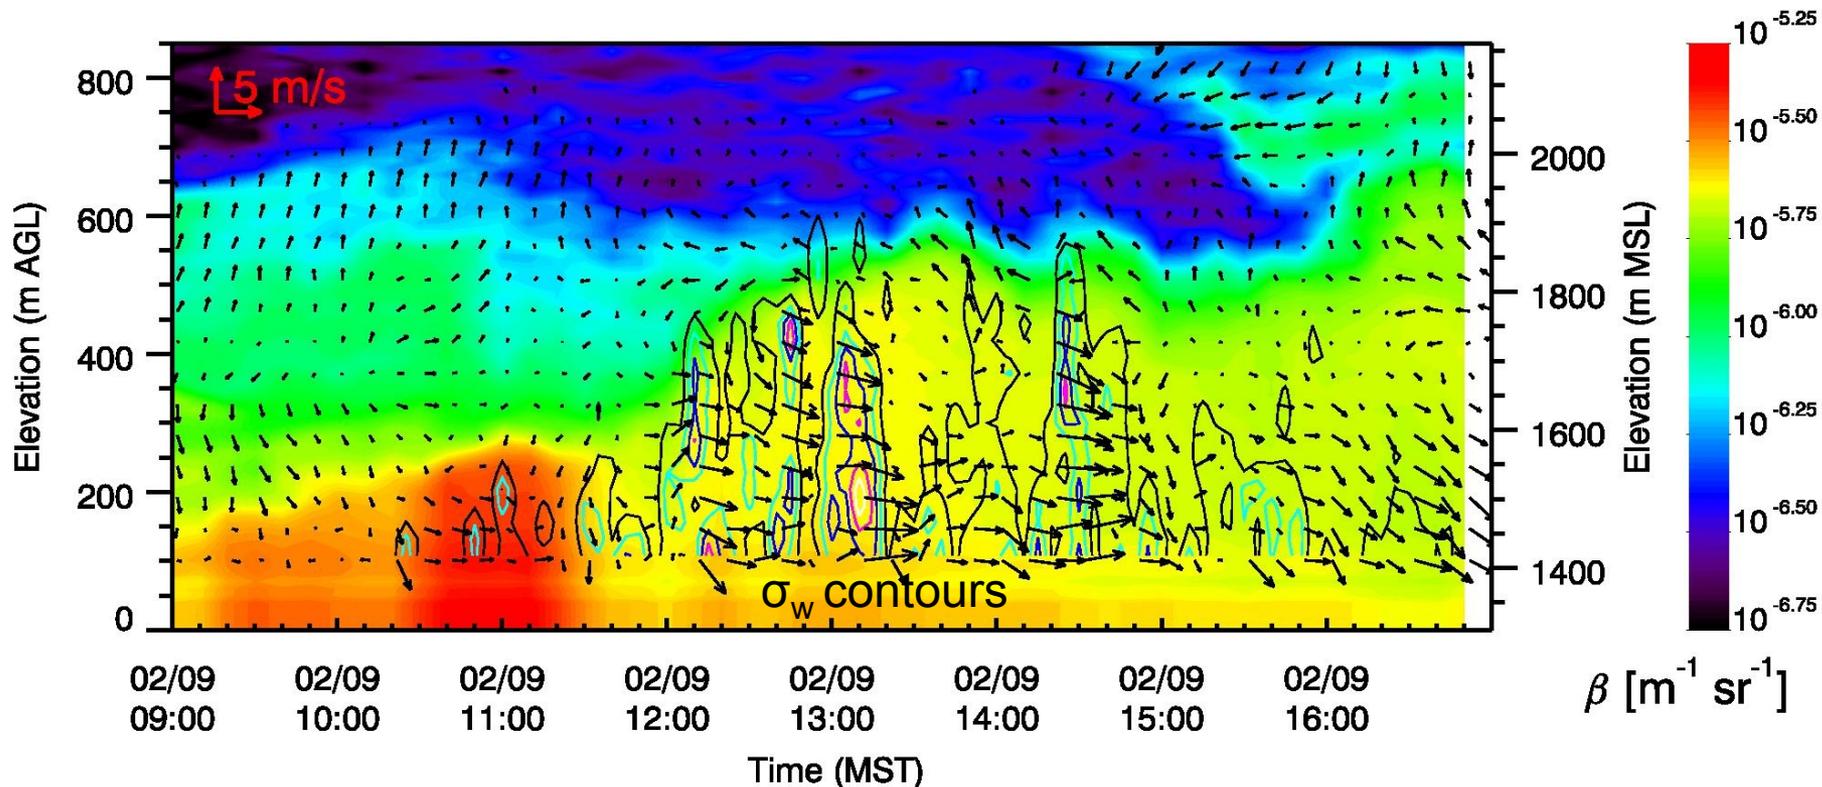

→ Higher O_3

Effect of drainage flows near the basin center

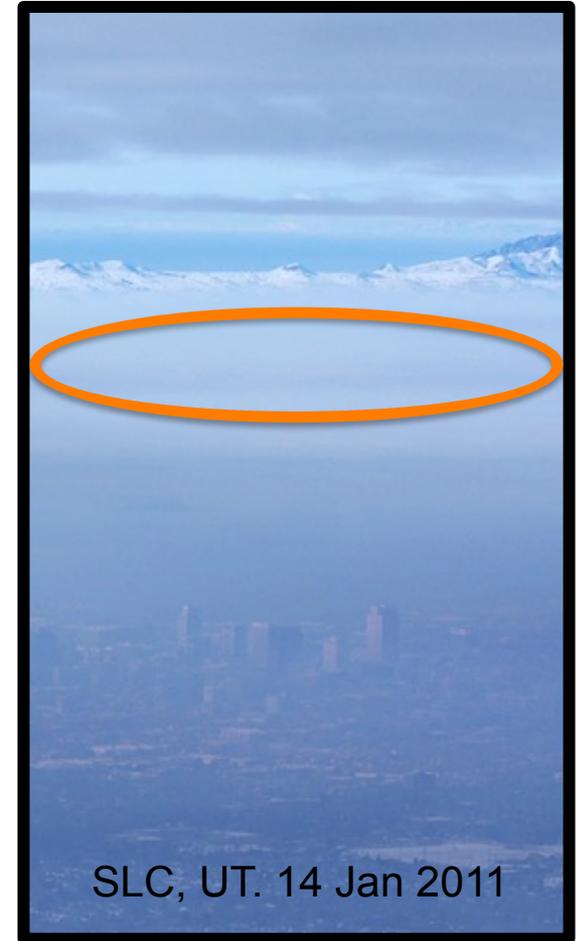

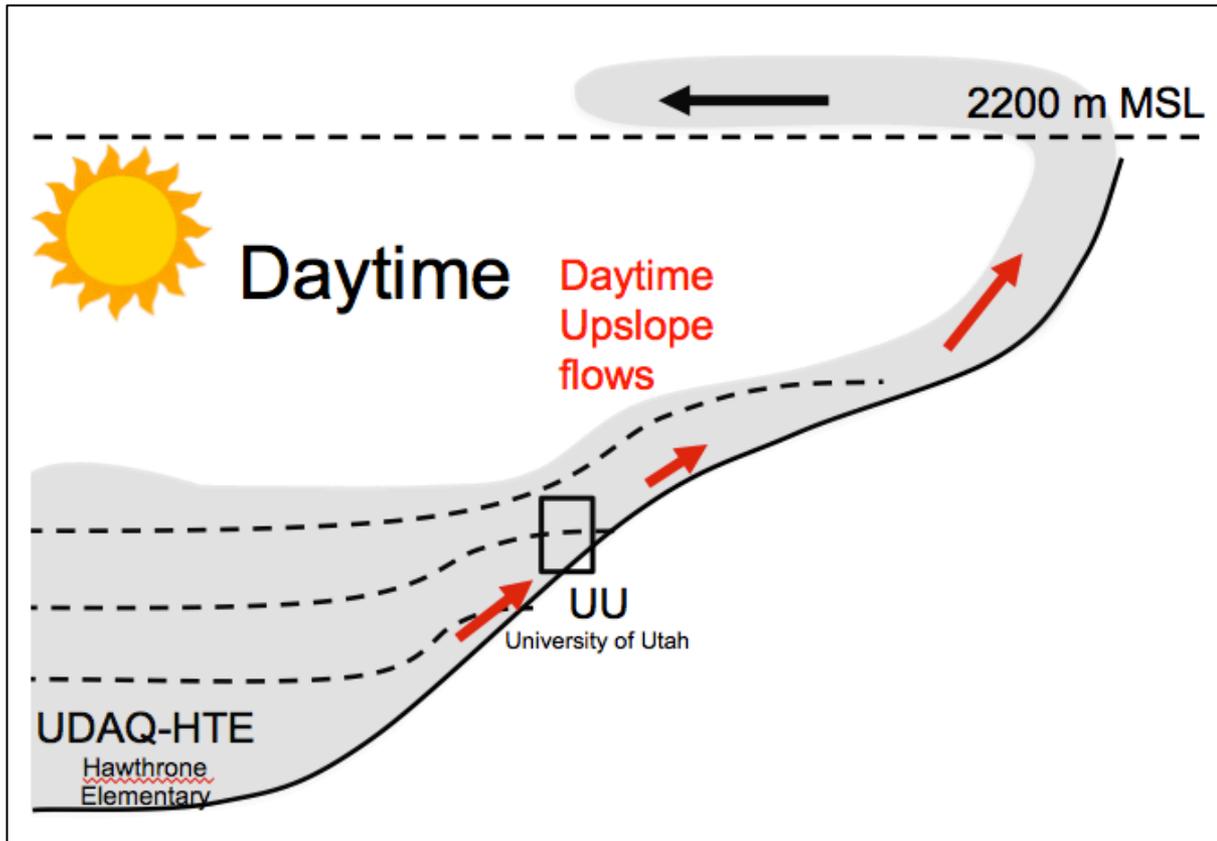

Time–height cross section of LiDAR wind, aerosol backscatter at Hawthorne Elementary

Daytime heating – Ventilation – Aerosol layering?

- σ_w (vertical velocity variance) from Lidar stares shows convection at the base of the PCAP

Daytime heating – Ventilation – Aerosol layering?

Pollution is ejected along the sidewalls into elevated layers and advected with the weak mean flow. → Ventilation

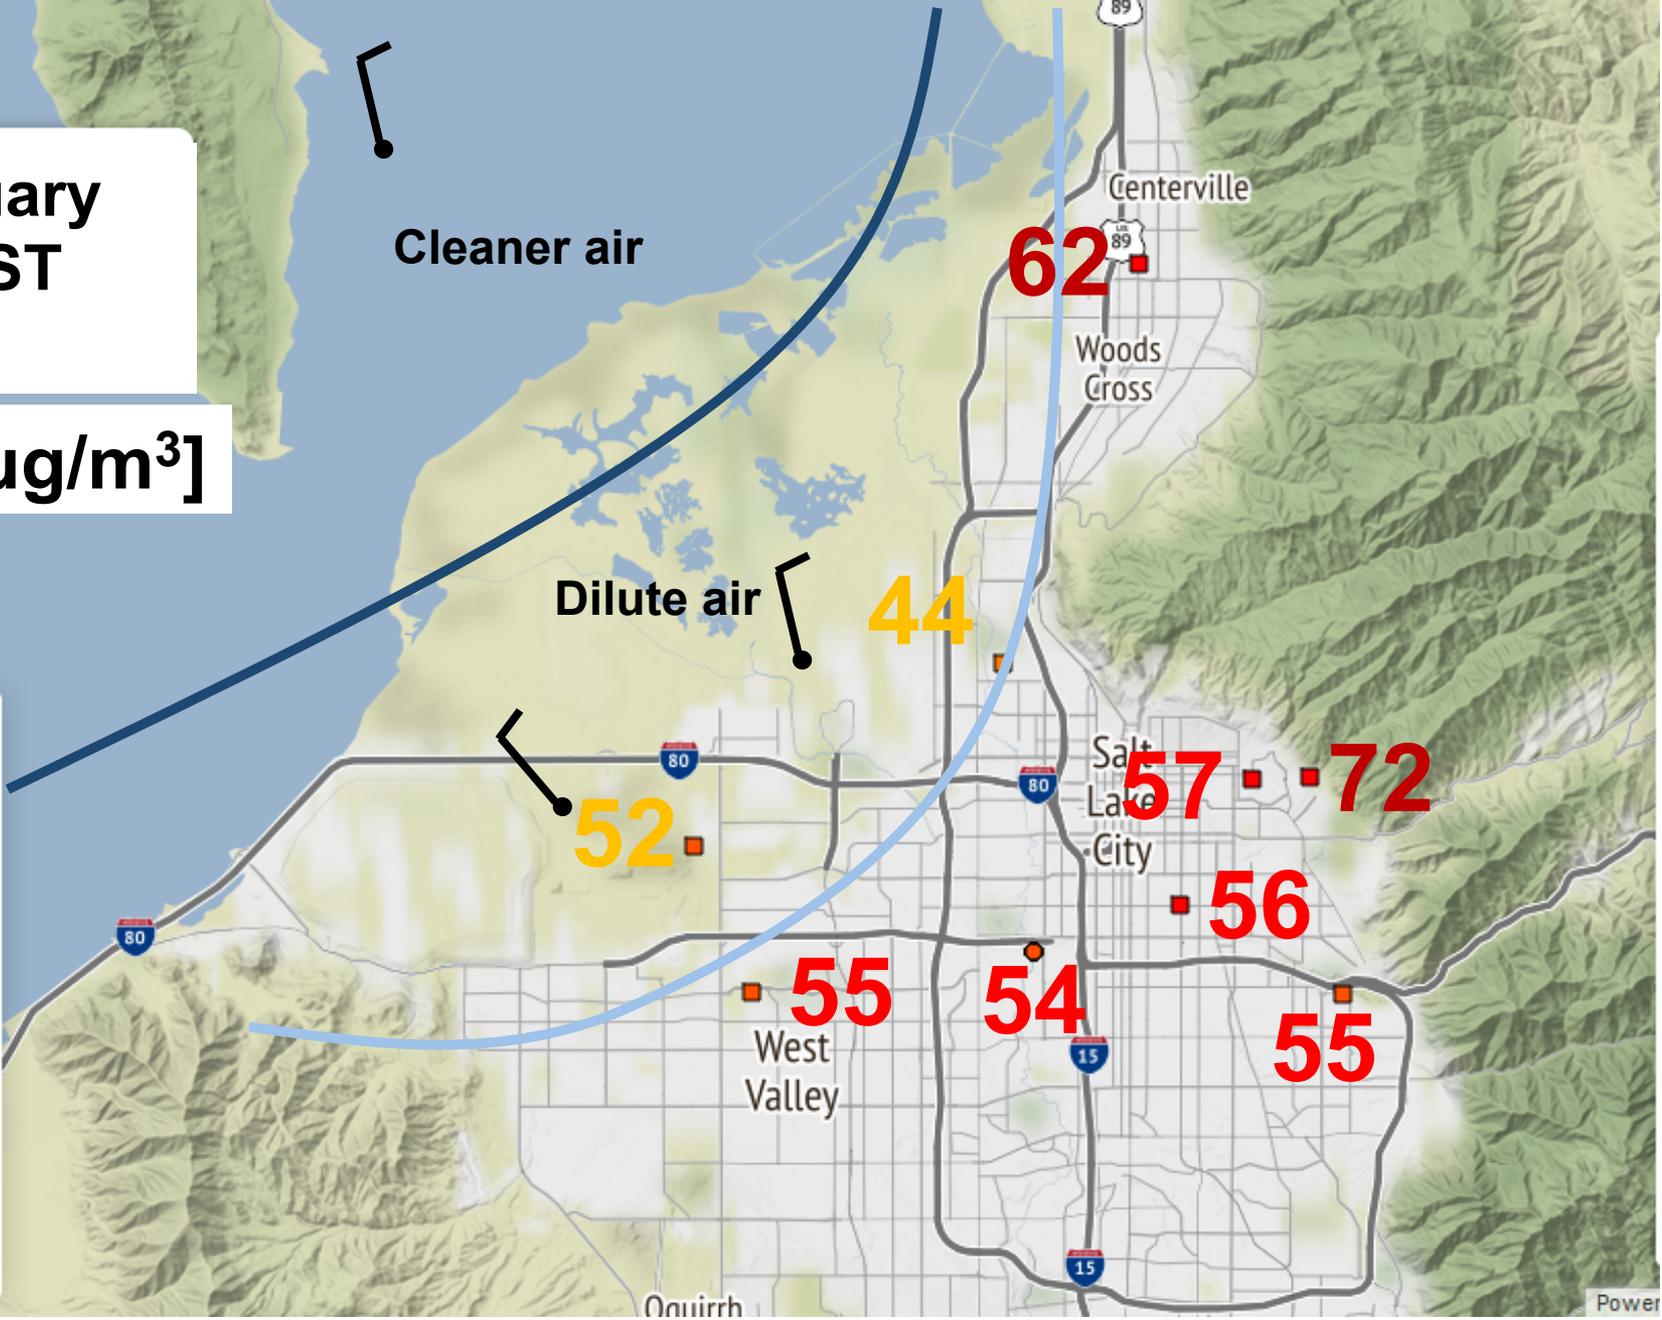

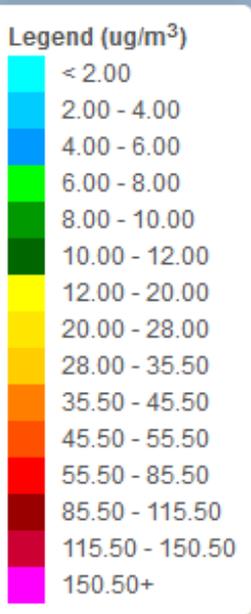

Lake Exchange Processes

Different air masses develop over the Great Salt Lake and the valley floor (water versus land surface)

**30 January

PM_{2.5} [$\mu\text{g}/\text{m}^3$]

3 February
0730 MST

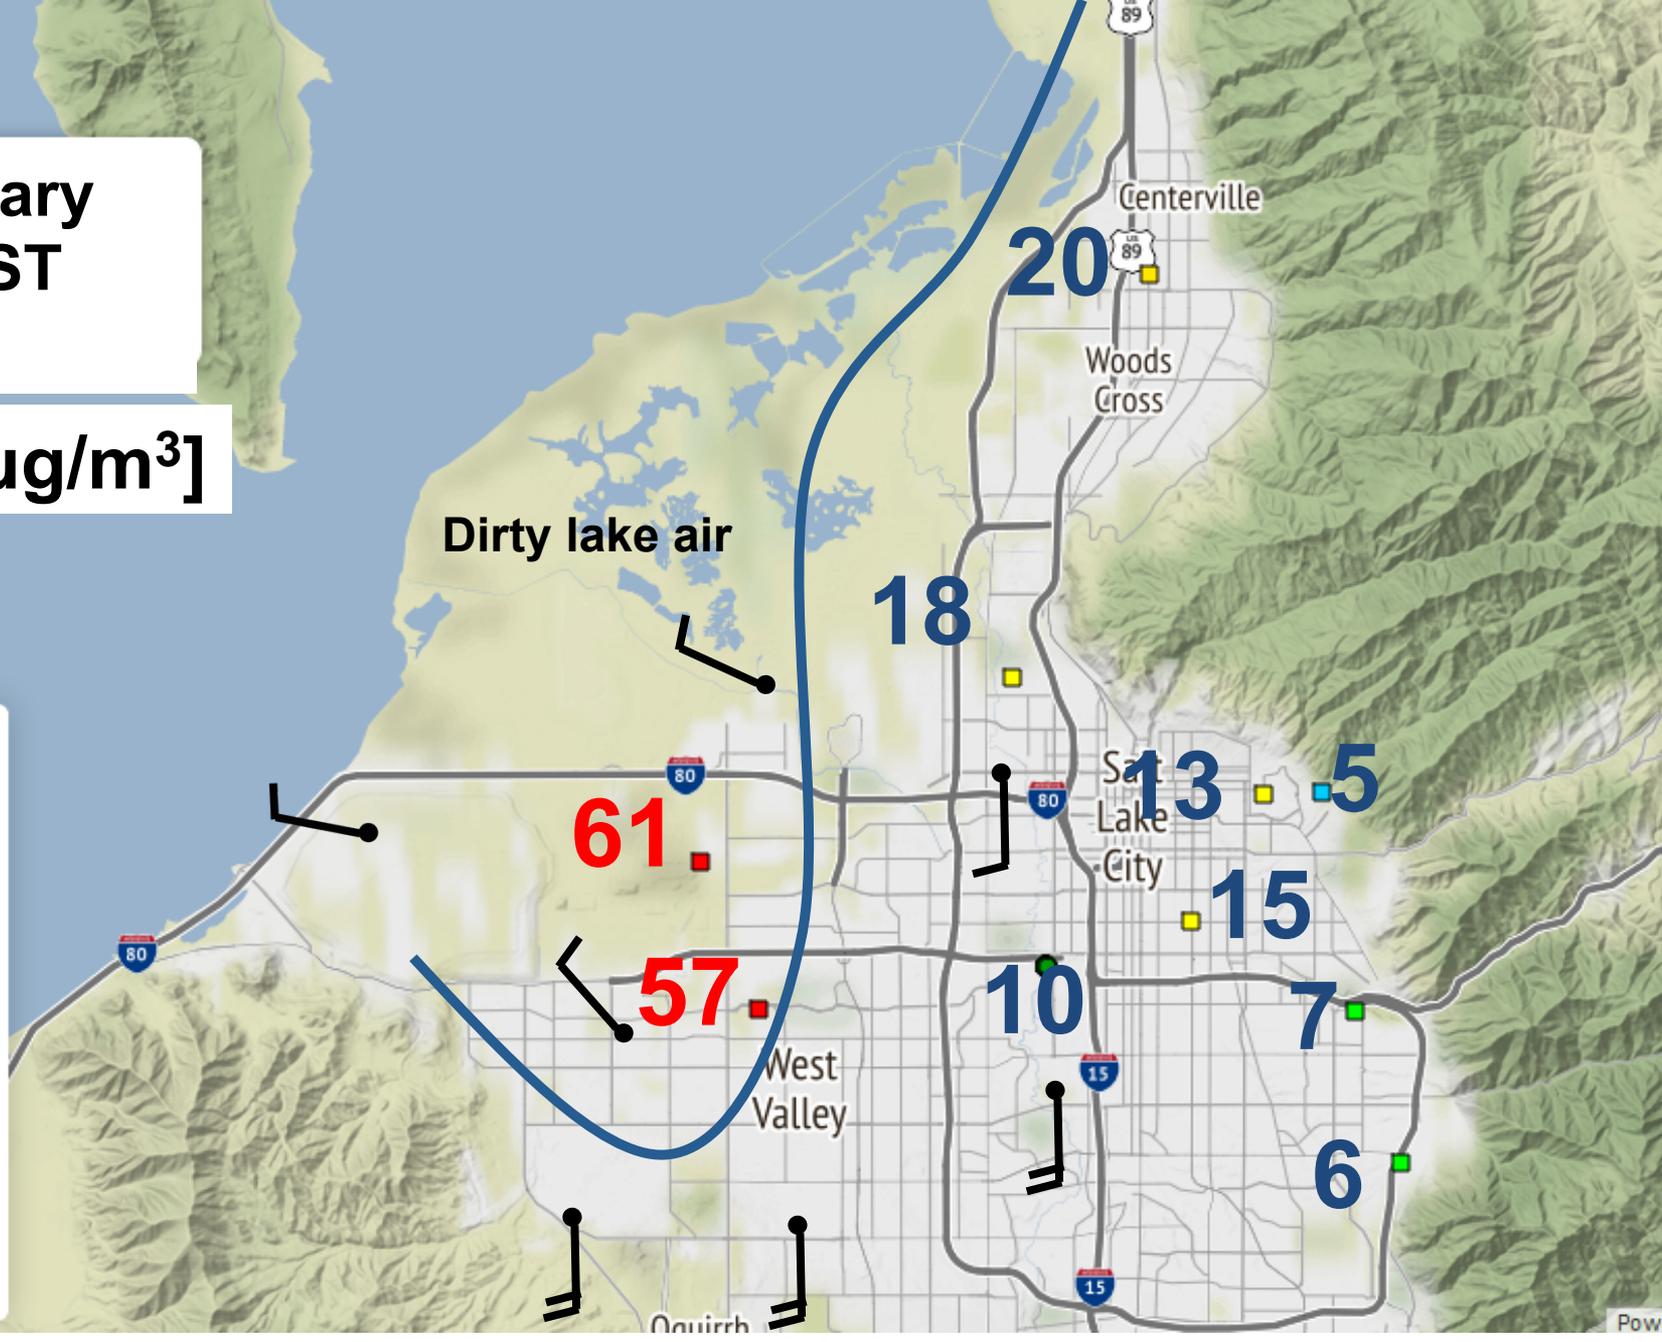

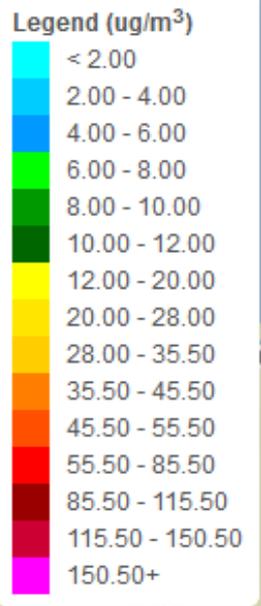

PM_{2.5} [$\mu\text{g}/\text{m}^3$]

**3 February
0900 MST**

PM_{2.5} [$\mu\text{g}/\text{m}^3$]

View from the “avenues”, 3 February 2017

Conclusions

- Meteorological processes play an important role in modulating particulate pollution concentrations during pollution episodes.
- These processes may directly affect concentrations but also indirectly by transporting oxidants necessary for secondary aerosol formation.
- Slope and valley flows bring cleaner and ozone-rich air into the cold pool at night.

Conclusions (cont.)

- During the day, pollution is transported up the tributary valleys. Some pollution may be ventilated into elevated layers.
- The air mass above the Great Salt Lake can serve as a reservoir of clean or polluted air. Air mass exchanges can modulate air quality significantly.
- Temporal and spatial variations in aerosol concentrations indicate that a single measurement at one location may not be representative for all areas in a populated basin.
